### Introduction

CBEP recently received a grant from NSF's CIVIC Innovation Challenge to work on developing hydrodynamic models that address community needs in Portland Harbor. As part of the project, CBEP hosted three community workshops in November of 2022.

Facilitators produced both "live" notes during the meeting – visible to all on a screen at the front of the meeting room – and detailed meeting transcripts. CBEP staff then reviewed those notes paragraph by paragraph, and coded each paragraph in terms of six characteristics:

- Potential users and uses of hydrodynamic models,
- Data or information needs identified by community members,
- Implied extensions of the initial Casco Bay Model required to fully address those data needs, and
- Ideas for improving communications of model results (e.g., communications channels and user interface design),
- Specifications for model performance or capabilities such as resolution, geographic coverage or ability to conduct simulations.
- Suggestions about monitoring or data collection that could improve information availability.

If a paragraph or live note included something relevant to one or more of these categories, we summarized the related idea, and then assigned each paragraph or comment to categories. In this way we cn look at what ideas were expressed most commonly during the workshops.

Of course, not all paragraphs include information related to each of the five types of information, so there is not a perfect one-to-one correspondence between categories.

In this R Notebook, I explore these data principally by looking at cross-correlations among ideas in the different categories.

# Load Packages

### Create Figures Folder

```
dir.create(file.path(getwd(), 'figures'), showWarnings = FALSE)
```

### Load Data

```

```

Our coding was generated in a somewhat sloppy Access database, and because of the way SQL works, it is easier to replace numerical values for some groups here, in R, rather than before we exported the data from Access. I read in the dictionaries here.

And finally I correct the data table to all text entries.

#A Warning about Uniqueness We have to be careful here, because each note or comment can be represented in this data table multiple times. Each paragraph in the meeting transcript might imply several different users, for example. But if there are multiple users and multiple data types, the records got duplicated (in part) in the SQL query. So for any analysis, we need to test for uniqueness of the data. always

We actually have over 400 records, built out of just over 200 unique comments.

```
cat("All rows in the data:\t\t")
#> All rows in the data:
nrow(the_data)
#> [1] 413

cat("Unique comments reviewed:\t")
#> Unique comments reviewed:
the_data %>%
  select(ID) %>%
  unique() %>%
  nrow()
#> [1] 206
```

# Sankay Plot Methods

We need to create a network data set, which has to identify links between notes by Source, Target and Value. The sankeyNetwork() function from the networkD3 package on which we rely wants the data in a very specific format.

- It wants to define NODES via a data frame of node labels (and, optionally, node groups that can be used to assign colors to nodes).
- It wants to define links via a data frame containing NUMERIC (integer?) values identifying nodes. The data frame can also include data on link groups for assigning colors to links.
- The integers defining each node must match the order of those nodes in the nodes data frame.

#### **Data Wrangling**

For clarity, I break the data wrangling up into discrete steps. That simplifies both explanation and checking intermediate results.

First, we select the user and data information.

We are headed for a display that shown User or Use groups on the left, and Data groups on the right. Both User and Data classifications included a category called simply "Other", for comments that clearly articulated a data request that I could not figure out how to categorize.

Sankey plots need not be unidirectional, so logically, nodes are neither sources nor targets. If I use the same name for both the "User Other" and the "Data Other" categories, the package sees them as the same category, which has unintended effects on plot geometry (since we can then have "Other" as either or both a source or a target.

TO avoid that problem, we have to edit the category names so the two "Other" categories don't look equivalent.

Finally, we convert the (string) data to factors, and sort them in decreasing order of frequency, which may help with later graphic design.

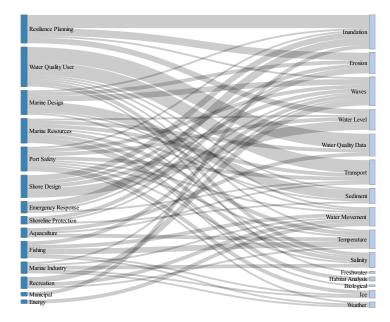

We next calculate the number of links between each pair of source and target nodes.

I add a groups variable, to allow me to control the color of the source and target nodes in the diagram.

Then we have to convert the character string values in our links data frame (tmp2) to zero-valued numerical IDs, as required by the networkD3 package.

match() here is a quick way of implicitly extracting the row number of a matching record from each vector (column) in the tmp2 data frame.

### Initial Graphic

#### **Custom Colors**

It might be nice to color the nodes or links according to categories. This is surprisingly difficult, because the package uses one color scale for both notes and links.

I found it hard to figure out how colors were ordered, and then found it hard to assemble the correct color specification as required for network3D.

I generate new node group names. For the "Source" nodes, we use the name of the user category. For the "Target" nodes, we use an arbitrary string, here "B".

We want the links to match the color of the source nodes, so we specify matching color group names for links based on the source (here, left hand) nodes.

Now I have to define my color palette. This is more work than it should be because you have to encapsulate a D3 graphics command in a string so that the sankeyNetwork() function can pass it on to the underlying Java / D3 code.

The command requires you to define the names and the colors together as the domain and range of the palette.

I randomize color order to minimize conflict with adjacent nodes. I specify the last color – for the right hand nodes – as a medium gray.

```
domain = c(users, "B")
(grps <- length(domain))
#> [1] 15
range <- sample(hcl.colors(15, palette = "viridis"), grps - 1, replace = FALSE)
range <- c(range, "#9090c0")
range
#> [1] "#008A98" "#FDE333" "#471D67" "#25C771" "#3C3777" "#4B0055" "#009B95"
#> [8] "#1E4D85" "#D4E02D" "#A6DA42" "#00BA82" "#006290" "#007796" "#73D25B"
#> [15] "#9090c0"
```

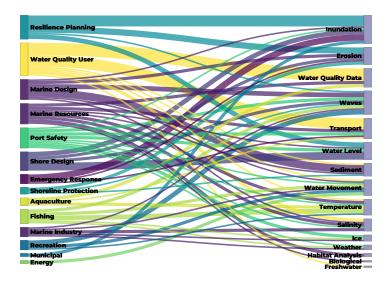

In the next step I build a data frame containing the domain and range. It is probably not strictly necessary, but it did avoid some odd artifacts with escaped quotes.

```
#> 1 Resilience Planning #008A98
#> 2 Water Quality User #FDE333
#> 3 Marine Design #471D67
#> 4 Marine Resources #25C771
                      #3C3777
#> 5 Port Safety
#> 6 Shore Design #4B0055
#> 7 Emergency Response #009B95
#> 8 Shoreline Protection #1E4D85
#> 9 Aquaculture #D4E02D
#> 10 Fishing
                       #A6DA42
#> 11 Marine Industry
                      #00BA82
#> 12 Recreation
                       #006290
#> 13 Municipal
                       #007796
#> 14 Energy
                       #73D25B
#> 15 B
                       #9090c0
```

The colors are assembles as a string, which takes some fussy work to do programmatically using paste(). Basically, I concatenate the text needed for the D3 function call with the lists of domain and range I just built.

### Revised Graphic

```
plt <- sankeyNetwork(Links = tmp3,</pre>
             Source = "User_Category",
             Target = "Data_Group",
             Value = "weight",
             LinkGroup = "link_group",
             NodeGroup = "groups",
             Nodes = nodes,
             NodeID = "node_name",
             colourScale = the_colors,
             nodeWidth = 20,
             nodePadding = 10,
             height = 700,
             fontSize = 16,
             fontFamily = 'Montserrat ExtraBold',
             iterations = 0)
#> Links is a tbl_df. Converting to a plain data frame.
#> Nodes is a tbl_df. Converting to a plain data frame.
plt
```

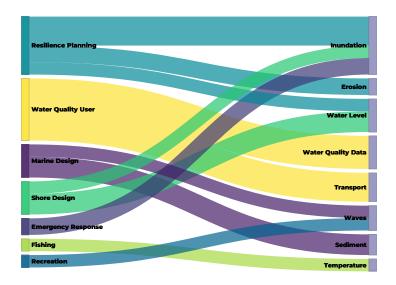

### Simplified Graphic

That graphic looks like a bowl of spaghetti. Most connections represent only one mention during the workshops. Since the data is based on both the live notes and the later transcript, one mention could show up either once or twice in my classification of the notes.

So, what I want to do is simplify the data by hiding all those "once or twice" links. It turns out if you drop rare links, a few nodes are never linked, so I want to drop them too.

```
plt <- sankeyNetwork(Links = tmp5,</pre>
             Source = "User_Category",
             Target = "Data_Group",
             Value = "weight",
             LinkGroup = "link_group",
             NodeGroup = "groups",
             Nodes = nodes,
             NodeID = "node_name",
             colourScale = the_colors,
             nodeWidth = 20,
             nodePadding = 10,
             height = 700,
             fontSize = 16,
             fontFamily = 'Montserrat ExtraBold',
            iterations = 0)
\# Links is a tbl\_df. Converting to a plain data frame.
\#> Nodes is a tbl\_df. Converting to a plain data frame.
plt
```

### Functions for Generating the Graphics

I develop three functions to encapsulate all of that logic. All three are local utility functions, so I eschew error checking. The three functions are:

- 1. A function to assemble the D3 color function call
- 2. A function to convert our source data frames, with a column of source and target names, into the format required by sankeyNetwork().
- 3. A function that actually generates the Sankey Plot (and calls the other two functions).

### **Define Color String**

This function could be generalized to allow automated dropping of weak links.

```
d3_colors <- function(left_names, right_name, final_color = NULL) {</pre>
  #left_names is a vector of string node labels used for the source nodes.
  #right.name is the name for the (single) target node group.
  #final color is a string defining a color for the right (target) nodes.
  domain = c(left_names, right_name)
  grps <- length(left_names) + 1</pre>
  #browser()
  if(! is.null(final_color)) {
    range <- sample(hcl.colors(grps-1, palette = "viridis"), grps - 1,</pre>
                     replace = FALSE)
    range <- c(range,final_color)</pre>
  }
  else
    #print(qrps)
    range <- sample(hcl.colors(grps, palette = "viridis"), grps,</pre>
                     replace = FALSE)
  cols <- tibble(d = domain, r = range)</pre>
  the_colors <- paste0('d3.scaleOrdinal() .domain(["',</pre>
                        paste(cols$d, collapse='", "'),
                         '"]) .range(["',
                        paste(cols$r, collapse='", "'),
                         ""])')
  return(the_colors)
```

```
d3_colors(c("cat", "dog", "squirrel"), "foods", "#ffffff")
#> [1] "d3.scaleOrdinal() .domain([\"cat\", \"dog\", \"squirrel\", \"foods\"]) .range([\"#009B95\", \"#
```

#### Assemble the Nodes and Links Data Frames

We have to be able to filter the data to remove rare I'm going to forego error checking here and keep this as simple as possible...

```
right_name = 'right') {
  # .data is the RAW data with left-right string pairs (in two variables) that
  # show a link between source (.left) and target (.right).
  grouped <- .dat %>%
   group_by({{ .left}}, {{.right}}) %>%
    summarize(weight = n(),
             .groups = 'drop')
  # browser()
  # there is probably a more efficient way to extract labels, that avoids
  # building an unnecessary data frame, but this works, and lets me use
  # tidyverse indirection....
  labs <- grouped %>%
   mutate(left = factor({{ .left}}),
          right = factor({{.right}}))
  #I can ignore order here because the Sankey function does....
  # By calling `factor()` here, it re-levels and drops empty categories.
  left = levels(factor(labs$left))
  right = levels(factor(labs$right))
  rm(labs)
  nodes <- tibble(node_name = c(left, right),</pre>
                 groups = c(left,
                            rep(right_name, length(right))))
  links <- grouped %>%
   mutate(link_group = as.character({{.left}}),
          "{{.left}}" := match({{.left}}, nodes$node_name) - 1,
          "{{\.right}}":= match({{\.right}}\, nodes$node_name) - 1)
  return(list(Nodes = as.data.frame(nodes), Links = as.data.frame(links)))
}
test <- tmp %>%
  assemble_frames(User_Category, Data_Group, 'bicycle')
test$Nodes[10:20,]
                                groups
#>
              node name

### Draw Sankey Plot

This encapsulates data frame preparation, color assignment and my selected plot characteristics.

```
my_sankey <- function(.dat, .left, .right,</pre>
                       final_color = NULL, drop_below = NULL) {
  right_name <- 'right'
  left_str <- as.character(ensym(.left))</pre>
  right_str <- as.character(ensym(.right))</pre>
  if (! is.null(drop_below)) {
    .dat <- .dat %>%
      group_by({{.left}}, {{.right}}) %>%
      mutate(links = n()) %>%
      filter(links >= drop_below)%>%
      select(-links)
  }
  my_data <- assemble_frames(.dat, {{.left}}, {{.right}},</pre>
                              right_name = right_name)
  left <- my_data$Links %>%
    mutate(left = as.character(link_group)) %>%
    pull(left)
  left <- unique(as.character(left))</pre>
  the_colors <- d3_colors(left, right_name = right_name,</pre>
                           final_color = final_color)
  #browser()
  the_graphic <- sankeyNetwork(Links = my_data$Links,</pre>
             Source = left str,
             Target = right_str,
             Value = "weight",
             LinkGroup = "link_group",
             NodeGroup = "groups",
             Nodes = my_data$Nodes,
             NodeID = "node_name",
             colourScale = the_colors,
             nodeWidth = 20,
             nodePadding = 10,
             height = 700,
             fontSize = 28,
             fontFamily = 'Montserrat ExtraBold',
```

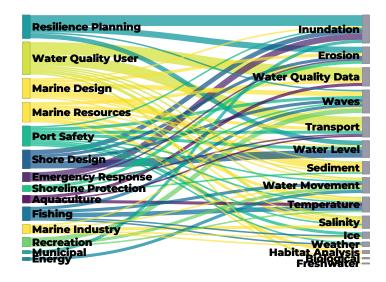

```
iterations = 0)
return(the_graphic)
}
```

### From User to Data Types

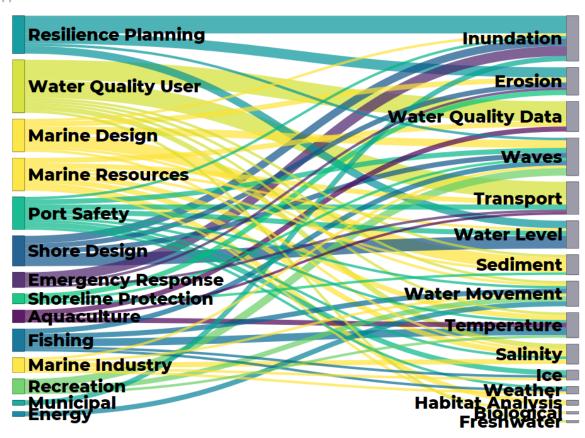

#### Full Data

Based on data organized previously.

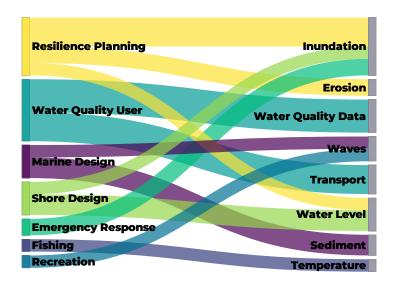

```
plt <- tmp %>%
  my_sankey(User_Category, Data_Group, final_color ="#9090a0")
plt
```

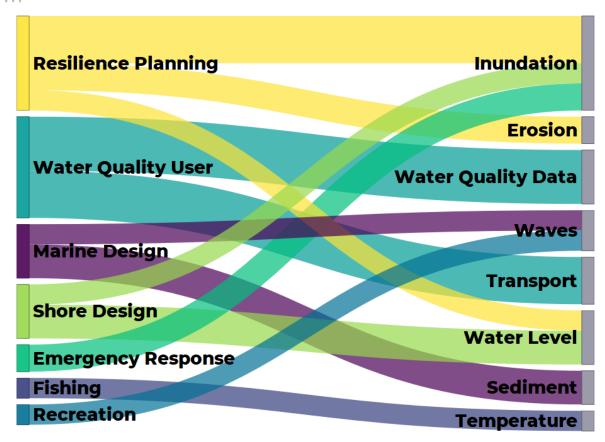

```
saveNetwork(plt, file = 'figures/users and data.html', selfcontained = TRUE)
webshot('figures/users and data.html', 'figures/users and data.png')
```

```
plt <- tmp %>%
   my_sankey(User_Category, Data_Group, final_color ="#9090a0", drop_below = 3)
plt
```

Tourism
                                               Specific Request
                                                     A Nice API
```

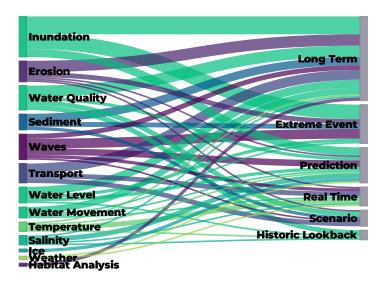

Not very useful....

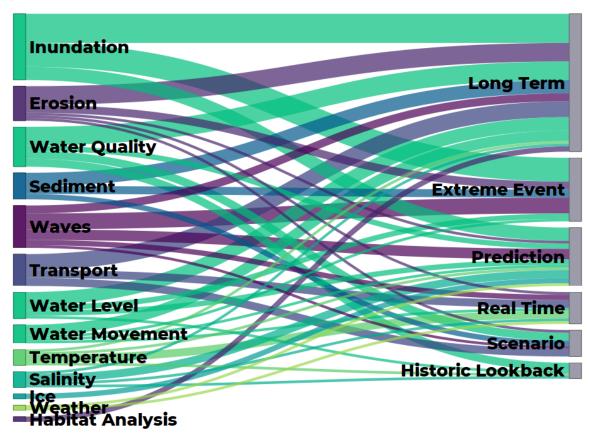

# From Data Requests to Time Domain

### Full Data

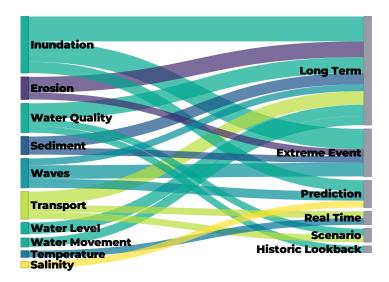

plt

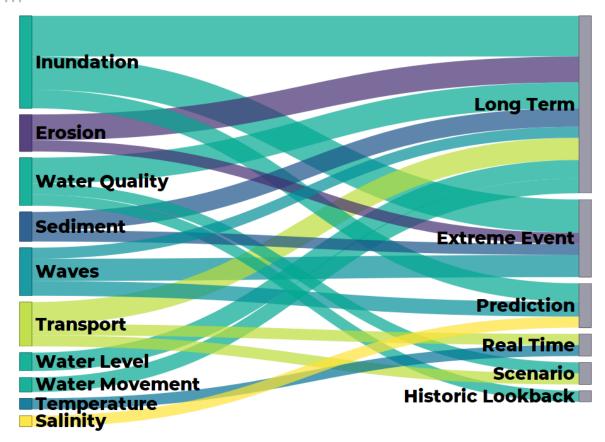

```
saveNetwork(plt, file = 'figures/data to timing.html', selfcontained = TRUE)
webshot::webshot('figures/data to timing.html', 'figures/data to timing.png')
```

```
plt <- tmp %>%
  my_sankey(Data_Group, Data_Timing, final_color ="#9090a0", drop_below = 3)
plt
```

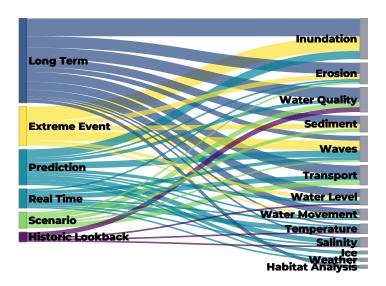

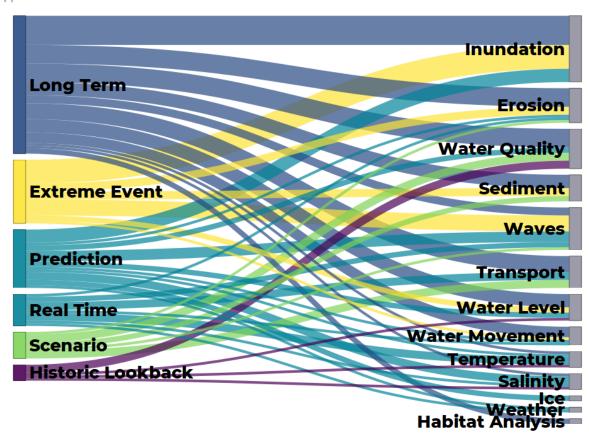

# From Time Domain to Data Requests

### Full Data

```
plt <- tmp %>%
  my_sankey(Data_Timing, Data_Group, final_color ="#9090a0")
plt
```

```
saveNetwork(plt, file = 'figures/timing to data.html', selfcontained = TRUE)
webshot::webshot('figures/timing to data.html', 'figures/timing to data.png')
```

```
